Revisão Bibliográfica

26 JUL DE 2018

# Introduction

- Project initial objective - CO2 leakage detection.
- Project modification - CO2 leakage quantification.

# Leakage Detection

- Workshop 2017, 2018 - Building capability for in situ quantitative characterisation of the ocean water column using acoustic multibeam backscatter data.

- STEMM-CCS - Strategies for Environmental Monitoring of Marine Carbon Capture and Storage (<http://www.stemm-ccs.eu/>)

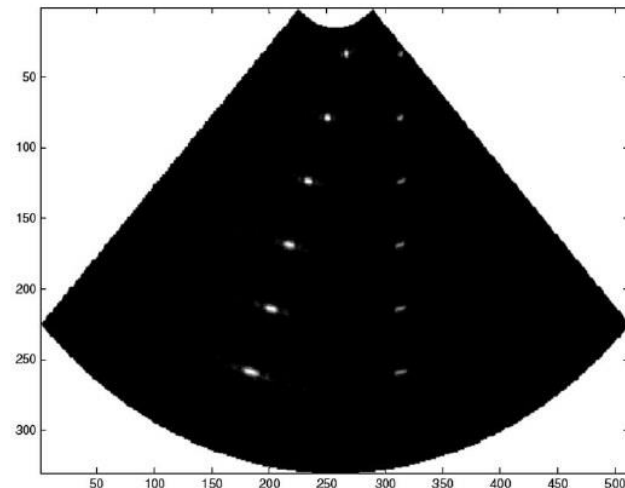

# Leakage Quantification

- Use of a side scan sonar with multi beam echosounder to quantify CO<sub>2</sub> leakages.
- Find a relationship between the bubble size and the CO<sub>2</sub> volume.
- Estimate the CO<sub>2</sub> volume from the bubble rise velocity.

# Noise Reduction (coherence factor)

- Compares the phases of the signals captured by each transducer element. When the phases are almost the same: factor near 1. When the phases are very different: factor near 0.
- The image is multiplied by the factor, reducing the noise.

# Noise Reduction (Inverse problem)

- Given an image, search for a spacial distribution of reflectors that generate a simulated image nearest to the input image (optimization problem).
- Possibility of quantitative results (reflectivity).
- Reduction of side lobe noise.
- Challenges: Sonar images are very large, and the medium is not uniform (e.g. variation in temperature).

# Numeric simulation

- The development of a simulation of acoustic signals generated by a sonar has been started.
- Uses the properties of a linear system (superposition).
- Decomposes the transducer and the reflector into a set of point sources/reflectors/receivers.

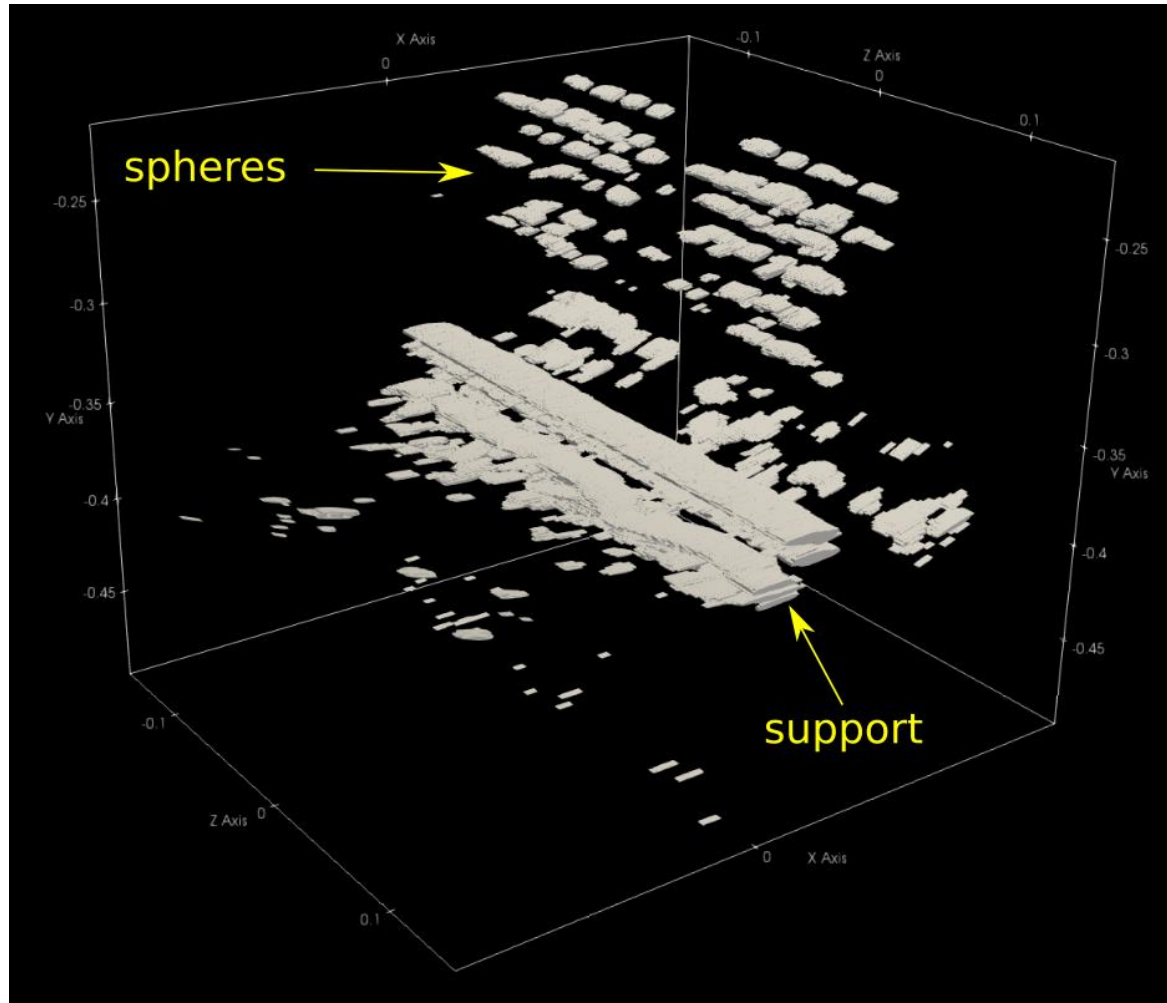

# Experimental simulation

- Bubbles simulated using expanded polystyrene spheres supported by stainless steel wires.

# Experimental simulation

# Experimental simulation

- Controlled injection of air bubbles using syringe needles with different internal diameters.
- Amount of air injected controlled by a pressure valve.

# Experimental simulation
